1 Introduction

The Innovation Fund (IF) supports projects in energy-intensive industries, carbon capture and utilisation (CCU), carbon capture and storage (CCS), energy storage and renewable energy.

The methodologies for the calculation of the GHG emission avoidance are described in the following sections:

1) Energy-intensive industries, including carbon capture and use, and substitute products
2) Carbon capture and storage
3) Renewable energy, including production facilities for components
4) Energy storage, including production facilities for components

Each section details the methodology to be used when:

1) applying for an Innovation Fund grant at first and second stage;
2) reporting performance for the purposes of disbursement of 60% of the grant that is linked to GHG emission avoidance; and
3) reporting performance for the purposes of knowledge-sharing.

1.1 Calculation of GHG emission avoidance compared to reference scenario

The calculations of GHG emission avoidance as well as relevant costs should comprehensively cover the impacts from the changes in inputs, processes, and outputs between the project and the reference scenario.

The reference scenarios should reflect the current state-of-the-art in the different sectors, as shown in Table 1.1 and Table 1.2.

### 1.1.2 GHG emission avoidance

The methodology is able to assess projects concerned with the avoidance of GHG emissions in the use and end-of-life phase of products, as well as to account for process inputs such as biomass, biofuels, intermediate products and by-products of other processes, wastes, and the use of some feedstocks or process chemicals that are outside the scope of the EU Emissions Trading System (EU ETS).

For instance, for projects involving the production of low-carbon products, GHG emission avoidance will also take into account emissions from inputs also from outside EU ETS boundaries, and end-of-life emissions. However, emissions for fossil fuel refining, extraction and transport have been disregarded from the methodology, for consistency with EU ETS.

### 1.1.3 Relationship to calculation of relevant costs

Applicants should be aware that the reference product or process used as the basis for relevant costs calculations will differ in some cases to that used for the reference GHG emission avoidance calculations. This is because the methodologies used as a reference for estimating GHG emission avoidance derive from widely recognised methodologies for each case, which do not necessarily define the boundaries in the same way as one would define the financial model for the purposes of calculating relevant costs.

### 1.2 Specification of a sector for the purpose of the GHG emission avoidance calculations

The applicant needs to choose a sector (see Appendix A1.4) when submitting the application. This choice will influence the points to be awarded for the first criterion on the potential of GHG emission avoidance:

- The calculated value of absolute GHG emission avoidance will be compared to the largest absolute GHG emission avoidance among submitted projects in the chosen sector.

- To calculate the relative GHG emission avoidance, the project’s absolute value of GHG emission avoidance will be compared to the GHG emissions in the reference scenario from the chosen sector.

The application may only be submitted for one sector.

In case that a project will earn revenues from the sale of a single product (e.g. steel, solar electricity), it will be straightforward to choose the according sector. Where a product will substitute another one of different composition (for example, ethanol to substitute gasoline in transport, rather than ethanol as a fine chemical), the relevant sector of the substituted product may be chosen (the refinery sector in this case).

In the case that a project will earn revenues from the sale of several products, the applicant should define the ‘principal product(s)’. The principal product(s) should reflect the main aim of the project: is the project e.g. designed to principally save emissions in the steel industry, or to make alternative transport fuel (as a by-product of steelmaking)?
If multiple products are in the same sector (e.g. a CCU process may produce gasoline, diesel, kerosene and fuel oil), the applicant can consider all or some of them as the ‘principal products’. The applicant can also only choose only one ‘principal product’. This choice of principal products will influence the estimate of the project’s relative GHG emission avoidance (see section 2.3).

If multiple products are in different sectors (e.g. a steel producer that proposes a project to produce recycled carbon fuel ethanol for transport alongside steel), the applicant will need to choose the sector to which the ‘principal product(s)’ belong and claim the absolute GHG emission avoidance from the project in this sector. The relative GHG emission avoidance will also need to be calculated based on the chosen ‘principal product(s)’.

The concept of “functions” is added, because some new products may not be identical to existing ones, but provide the same functions. Thus, for example, if a new process produces a stronger plastic that enables bottles to be made twice as thin, the throughput of the reference plastic-producing process must be double that in the project scenario.

1.3 GHG emission avoidance calculation

The GHG emission avoidance is equal to the difference between the emissions from the project activity and a reference scenario over a defined period. Applicants shall carry out two calculations: a simpler one at the first stage and a more detailed one at the second stage.

1.3.1 Absolute GHG emission avoidance

The absolute GHG emission avoidance is calculated based on the expected emissions avoided in each year from the start of the operation over a 10 years period, using the equation below.

\[ \Delta \text{GHG}_{\text{abs}} = \sum_{y=1}^{10} (\text{Ref}_y - \text{Proj}_y) \]

Where \( \Delta \text{GHG}_{\text{abs}} \) represents the net absolute GHG emissions avoided due to operation of the project during the first 10 years of operation. \( \text{Ref} \) the GHG emissions that would occur in the absence of the project in year \( y \) and \( \text{Proj} \) the GHG emissions associated with the project activity and site in year \( y \).

1.3.2 Relative GHG emission avoidance

The relative GHG emission avoidance potential will be calculated by comparing \( \text{Proj} \) the GHG emissions associated with the project activity and site and \( \text{Ref} \) the GHG emissions that would occur in the absence of the project over a 10 years period.

\[ \Delta \text{GHG}_{\text{rel}} = \frac{\Delta \text{GHG}_{\text{abs}}}{\sum_{y=1}^{10} (\text{Ref}_y)} \]

where:

- \( \Delta \text{GHG}_{\text{abs}} \) = Net absolute GHG emissions avoided due to operation of the project during the first 10 years of operation, in tCO\(_2\)e.
- \( \Delta \text{GHG}_{\text{rel}} \) = Relative GHG emissions avoided due to operation of the project during the first 10 years of operation, in percent.
- \( \text{Ref}_y \) = For energy storage, carbon capture and storage, renewable energy and industrial projects where there are no products other than the "principal products" = GHG emissions in the reference case in year \( y \) (t CO\(_2\)/yr).
For industrial projects with multiple products = the part of the GHG emissions in the reference case in year \( y \) (t CO\(_2\)/yr) that are attributed to the chosen “principal products”. This is explained further in section 2.3.

\[
\text{Proj}_y = \text{Additional GHG emissions due to the operation of the project in year } y \text{ (t CO}_2\text{/yr)}
\]

In case that the project operates for less than 10 years, \( \Delta \text{GHG}_{\text{rel}} \) will be set to zero for those years \( y \) in which the project does not operate. Applicants may also consider an expected ramping up period, i.e. reduced performance over the first years due to necessary stops and starts of the production for technical adjustments. Therefore, the calculations in the second stage do not necessarily need to lead to the same result as in the first stage. All the above considerations should be duly explained and justified in the description of the calculations.

There are also specific simplifications in the different categories, which will result in more accurate calculation of emission avoidance in the second stage.

Applicants may combine activities related to two or more eligibility categories (energy-intensive industries, CCS, RES, energy storage), to be referred to as hybrid projects. Hybrid projects shall calculate the absolute GHG emission avoidance and the project emissions according to the individual methodologies and add these up while removing double counting of avoidance and/or emissions, if any. The relative GHG emission avoidance shall be calculated based on the cumulated emission avoidance and the cumulated project emissions. Any project including intermittent use and/or generation of electricity at times when there is an excess of renewables in the grid-mix (e.g. smart grid applications) will need to resolve the demand profile into a continuous component plus a virtual storage activity as explained in the section on energy-intensive industries (see Section 2.2.3.4), in order to make sure the proper emission factors are applied to its electricity demand, generation and storage.

### 1.3.3 Greenhouse gases considered

The greenhouse gases that must be taken into account in emissions calculations shall be at least those listed in the EU ETS Directive, Annex II: carbon dioxide (CO2), methane (CH4), nitrous oxide (N2O), hydrofluorocarbons (HFCs), perfluorocarbons (PFCs), sulphur hexafluoride (SF6). The Global Warming Potentials (GWP) to be used are those in the Annex to Commission Delegated Regulation supplementing Regulation (EU) 2018/1999 of the European Parliament and of the Council with regard to values for global warming potentials and the inventory guidelines and with regard to the Union inventory system and repealing Commission Delegated Regulation (EU) No 666/2014.

### 1.3.4 Emissions generally excluded

Generally, the following emissions are excluded for all projects unless specified otherwise:

- Emissions from capital goods (i.e. manufacture of machinery and equipment).
- Emissions due to the extraction, processing, transportation and storage of fossil fuel are also excluded inasmuch as they contribute to the emissions attributed to material inputs to IF projects.

---

1 to be adopted after European Parliament and Council scrutiny and applicable as of 1/1/2021

2 This allows aligning with the methodology for calculating the EU ETS benchmarks, which considers only combustion emissions.
- Fugitive CO$_2$ and CH$_4$ emissions due to well testing and well bleeding in geothermal power plants.
- Combustion emissions for biomass, biogas, biomethane, biofuels and bioliquids.
- Indirect land use change emissions from supply of crops, and consideration of carbon debt in forestry.
- Decommissioning of the power plant and machinery at the End-of-Life (EoL).
- Emissions related to employee commuting, business travels and waste generation at the administrative offices.
- Biogenic CO$_2$ combustion emissions for biomass fuels. But emissions of non-CO$_2$ greenhouse gases (CH$_4$ and N$_2$O) from the fuel in use shall be included.

Should applicants wish to include any of the above emissions sources within the boundaries of reference and/or scenarios, these shall be quantified using the hierarchy of data sources specified in A1.3.

1.4 Simplifications for calculations in first stage

Various simplifications of the methodology are done for first stage of the application, which are explained in detail in the different sections. For example, for energy-intensive industry, in the first stage, the applicant may select a bigger share of inputs that are considered minor or de minimis and therefore can respectively derived from literature or disregarded. For renewable electricity and heat projects (except for bio-electricity and bio-heat), project emissions are disregarded in first stage. Similarly, for energy storage projects, on-site project emissions are excluded in the first stage.

1.5 Monitoring, reporting and verification of performance for disbursement and knowledge-sharing

During operation, beneficiaries will have to demonstrate GHG emission avoidance following the same assumptions that were made during the application for funding. Further requirements are introduced for the purpose of knowledge-sharing (KS), which will allow reporting on the actual emissions avoided during operation.

The general conditions on monitoring, reporting and verification (MRV) of performance, disbursement of the grant and knowledge-sharing are described in the call text. The respective sub-sections on MRV and KS therefore provides detail on the specific requirements for reporting for the purposes of disbursement and for knowledge sharing for the different categories.
2 Energy-intensive industries (EIs)

2.1 Scope

This section will deal with the approach to estimate GHG emission avoidance in projects, including CCU projects falling in the energy-intensive industry activities covered by Annex I of the EU ETS Directive. Also included are processes (such as ones based on biomass) whose principle products substitute products otherwise produced in these sectors.

The objective of this methodology is very different from the emission-saving methodology the Commission will propose for Renewable Fuels of Non-Biological Origin and Recycled Carbon fuels in RED2. The IF seeks to assess future emissions savings from innovations that are needed to reach climate goals in 2050, whereas the REDII estimates the "well-to-tank" emissions for fuels produced under current conditions, including current emissions attached to electricity consumption.

Thus eligible projects based on biomass must concern the processing that leads to the production of those products. In practice that means almost exclusively innovative processing of various types of biomass to biofuel, or innovative production of other bio-based products in bio-refineries.

At each application stage, each project will submit a block diagram based on Figure 2.1, with the boxes filled with the main items of relevance: inputs, processes, products, use differences (if necessary, the individual boxes may be expanded onto separate pages).

Due to the great variety of projects, no simplification of the diagram is foreseen for first stage. However, there are substantial simplifications in the calculation of emissions in the first stage as explained in the inputs section.

2.2 Absolute GHG emission avoidance

The life-cycle emissions from a project applying for the IF are evaluated by comparing a scenario including the proposed project, with a reference scenario without the project, as illustrated in Figure 2.1. The reference scenario provides the same products or functions as the project scenario.

The emissions avoided by the project, are those of the project scenario minus those of the reference scenario. Thus, if some processes, inputs, or outputs remain identical in the scenarios, there is no need to calculate their emissions. However, the scenarios include all components which are changed by the project.
It follows that if a project involves construction of a new plant, the reference scenario includes the alternative process(es) that provide the same or equivalent function(s) in the absence of the project. An “equivalent function” is usually the same quantity of an identical product made in the conventional way. However, if the new product does not have an identical equivalent, it would be the conventional product(s) that would fulfil the same function.

The change in emissions attributed to the project, $\Delta E_{\text{project}}$ is the sum of the change in its component parts, each of which may be positive or negative:

$$
\Delta E_{\text{project}} = \Delta E_{\text{inputs}} + \Delta E_{\text{processes}} + \Delta E_{\text{products}} + \Delta E_{\text{use}} + \Delta E_{\text{EoL}} \quad [1]
$$

In most cases, several of these components will be identical for the project and reference scenarios, and so their change in emissions can be simply set to zero.

It is only for convenience of the description that the calculation is broken down into inputs, processes, and products. As long as the products balance between the project and reference scenarios, the result would be the same whether, for example, emissions are represented as a major “input” or as additional “process” to make that input.

### 2.2.2 $\Delta E_{\text{process(es)}}$

#### 2.2.2.1 Definition of the processes in the project and reference scenarios

First, the applicant identifies all the processes associated with production of the chosen principal product(s) or functions, which are under the control of the applicant. The processes in the reference scenario must balance those principal products or functions.

Then, just those processes that are changed in the project scenario compared to the reference scenario need to be considered (a “change” in the process includes changes in the output (“activity level”) or in the emissions per unit output). Other inputs from processes that are outside the control of the applicant are to be dealt with in the “inputs” section. Differences between the other (“non-principal”) products between the project and reference scenarios are dealt with in section 2.2.4.

In the case of a project to modify an existing plant, the reference scenario may contain the unmodified process(es) (rather than the EU ETS benchmarks) provided that the total of...
emissions for the modified processes in the project scenario (calculated using the EU ETS methodology for assigning free allocations that is current at the time of submission of the application for the first or second stage) is less than the corresponding sum of EU ETS benchmark emissions for the years of operation of the project. The objective is to allow improvements to current plants without “locking in” high-emissions plants that emit more than the EU ETS benchmark.

For plants producing novel transport fuels falling under the definition of biofuels, Renewable Fuels of Non-Biological Origin (RFNBOs) or Renewable Carbon Fuels (RCFs) under REDII, the emissions for the equivalent quantity\(^3\) of substituted conventional fuel shall be the “IF fossil fuel comparator”\(^4\) of the substituted fuel in the following table minus the stoichiometric combustion emissions of the novel fuel (both expressed in gCO2e/MJ)\(^5\).

<table>
<thead>
<tr>
<th>Substituted fossil transport fuel</th>
<th>IF fossil fuel comparator (gCO2e/MJ)</th>
<th>LHV = NCV (MJ/kg)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Diesel</td>
<td>80.4</td>
<td>43.0</td>
</tr>
<tr>
<td>Gasoline</td>
<td>78.9</td>
<td>44.3</td>
</tr>
<tr>
<td>LPG</td>
<td>65.4</td>
<td>47.3</td>
</tr>
</tbody>
</table>

For new plants producing other products, the reference scenario shall be built as far as possible from sub-installations with product benchmarks defined in the applicable Benchmarking Decision at the time of the submission of the application for the first or second stage. When the boundaries of the processes in the project do not coincide with EU ETS product benchmark sub-installations, other ETS sub-installations are added to the process or reference scenarios to balance the products and account for all energy and material flows between sub-installations.

Each process and sub-process in the project scenario will be calculated by the applicant according to the current EU ETS methodology, and those from the reference scenario subtracted.

For projects whose processes are not entirely covered by (combinations of) EU ETS product benchmarks and sub-installation emissions, the choice of another reference process needs to be convincingly justified. This entails listing all the alternative reference processes that could reasonably be proposed, and then justifying (e.g. by examining the present market) why the chosen one is indeed the one most likely to provide the same products or functions in the absence of the project. The evaluators will check the comprehensiveness of the list and the validity of the arguments for the selection, as some LCA studies sponsored by applicants of a project select the reference scenario with the worst conceivable emissions, neglecting to mention lower-emission alternatives that may be more realistic.

---

\(^3\) For fuels that are blended into fossil transport fuel or used as their direct replacements in existing unmodified vehicle engines, the equivalent quantity of the substituted fuel is that with an equal lower heating value (LHV = net calorific value, NCV). For fuels (such as hydrogen) used in heavily modified vehicles, the equivalent quantity of substituted fuel is that which provides the same transport function (i.e. delivers the same kilometres x tonne of load), derived from v5 of the JEC-WTW report.

\(^4\) The IF fossil fuel comparator differs from that in REDII because the IF methodology (in order to align with EU ETS) does not consider the emissions from extraction and transport of crude oil, nor the transport and distribution of the final fuel.

\(^5\) This procedure corrects for any differences in combustion emissions expressed in gCO2/MJ fuel. As biomass-derived CO2 is not counted as an emission, no combustion emissions are subtracted in the case of biofuels.

\(^6\) These are not combustion emissions: they are not to be used as emissions factors for these fuels as inputs.
2.2.2.2 Calculating the change in process emissions

Except for the case of RFNBOs and RCFs, listed in the table above, the applicant must calculate the direct GHG emissions for the combination of processes in the project and reference scenarios using calculation methods specified in the Monitoring and Reporting Regulation\(^7\).

The emissions of biogenic CO\(_2\) from combustion of biofuels is not counted, which is consistent with the EU ETS and REDII Directives.

In addition, the applicant must specify the inputs that enter the boundary of the "processes" box of the product and reference scenarios in electricity inputs and material inputs which are not covered by EU ETS direct emissions calculations. This includes feedstocks that are residues or intermediate products of processes outside the control of the applicant, process chemicals not otherwise accounted for, biomass, bioliquids and biofuels. The emissions attributed to these changes is dealt with in the "inputs" section 2.2.3.

2.2.2.3 Changes in emissions from waste processing

Besides accounting for changes in emissions due to the use of wastes as an input, it is also necessary to account for any changes in emissions because of the change in the nature of wastes produced by a process. For example, an innovative process may eliminate a waste stream that requires energy-intensive treatment. These emissions are considered part of the process emissions step. Obviously, if there is no change, no calculation is needed.

2.2.2.4 Emission avoidance from carbon capture and geological storage (CCS)

If an IF project in the energy-intensive industry category includes permanent storage of some of its carbon dioxide emissions in accordance with Directive 2009/31/EC on the geological storage of carbon dioxide, the stored CO\(_2\) may be subtracted from the process emissions although any emissions associated with the capture, transport and storage operation are taken into account in the project emissions. See section 3 for details. In case that a third party carries out the transport or geological storage, the relevant contractual arrangements must be submitted.

2.2.2.5 Emission avoidance from CO\(_2\) capture and use (CCU)

Both CO\(_2\) capture and use inside the project

It is expected that most CCU projects will be of this sort. It is implicit in the "project – reference" methodology that if additional CO\(_2\), that was either in the atmosphere or about to enter the atmosphere, is both captured and incorporated in a product in an IF project, the captured CO\(_2\) is accounted as a reduction in emissions of the project. Similarly, any CO\(_2\) capture and use in the reference scenario must also be taken into account in deciding what CO\(_2\) capture in the project is additional. The emissions attributed to the capturing process, plus any emissions from transporting the CO\(_2\), are accounted as part of the overall process emissions.

Imported CO\(_2\)

Other CCU projects may use CO\(_2\) imported from a plant that is not under the control of the applicant. If the captured CO\(_2\) is an input from a known source outside the project and its carbon content incorporated into the product(s) of the project, the carbon incorporated into

---

the product(s) shall reduce the CO2 emissions attributed to the product, but the emissions from the capture and transport of the CO2 must be also included in the project emissions.

This results in essentially the same calculation as in section 3 on carbon capture and storage (without the emission involved in the storage of course). However, in industrial projects the CO2 could be imported either in gaseous or liquid form, whereas only liquid CO2 transport is considered in section 3.

If the CO2 is bought off the industrial gas market (and therefore in liquid form) from a producer who does not provide data, the emissions for the transport are included.

Projects proposing only CO2 capture but without any additional use of CO2

Under present and medium-term market conditions, far more CO2 is emitted, also in concentrated form, than is needed by industry. Therefore, an increase in the demand for industrial CO2 leads to more CO2 capture, but increasing CO2 capture without increasing its usage merely displaces capture of CO2 by another installation, with no overall avoidance of CO2 emissions.

Therefore, projects proposing capture of CO2 cannot subtract the amount of captured CO2 from the calculated project emissions, unless the additional use of that CO2 is also part of the project.

Use of geological CO2

If CO2 is being released naturally to the atmosphere (e.g. in a geyser), but a project captures it and then incorporates it in a CCU product, then the avoided natural CO2 emissions can be used to reduce the net emissions of the production process, which may end up negative as a result.

However, if the project provoked the release of the geological CO2 which would otherwise have stayed underground (e.g. by drilling for geothermal steam from a reservoir where it is mixed with CO2), then there are no avoided emissions, so it does not reduce the emissions of the production process.

Combustion/end of life emissions of CCU fuels/products

To avoid double counting, as the incorporation of captured CO2 in a fuel (or other product) is already counted as reducing the emissions attributed to its production (and could make them negative), it does not influence the combustion emissions attributed to the CCU fuel, (or, for another CCU product, its emissions in its use or end-of-life).

2.2.3 ΔE_inputs

Inputs are any energy or material flow into the boundary of the process box in a scenario. ΔE_inputs is the change in emissions arising from changes in the inputs to processes, between the project and reference scenario, so any inputs that are quantitatively and qualitatively the same in the two scenarios can be ignored here.

In fact, ΔE_inputs results only from changes in the amount of the inputs or “activity level”. That is because the production of these inputs is by definition outside the control of the project, so the emissions factor (e.g. tonnes CO2e/tonne input) attached to a given input must be the same for the project and reference scenarios.

As the objective of the Innovation Fund is to support future breakthrough technologies that will help EU reach climate neutrality in 2050, for the purposes of the GHG emission

---

8 It is essential that the CO2-use is integrated in the project boundary because almost always very considerable additional emissions are spent in transforming the CO2 into a useful product, and these emissions will disappear if the use of the CO2 is split off.
avoidance calculation, where electricity is fed from the grid to a project, it should be assumed that electricity sector is fully decarbonised, i.e. the emission factor for the electricity consumed is zero.

Innovative solutions to procure renewable electricity for the operation of the project will be an important element for the evaluation of the criterion “Degree of innovation”. In particular, as several industry projects will use significant amounts of electricity, the applicants should consider how to ensure that electricity is fully of renewable origin and not to increase grid congestion (which could otherwise prevent additional renewable electricity reaching the project). With regard to transport fuels of non-biological origin (e.g. hydrogen, e-fuels), Directive (EU) 2018/2001 on the promotion of the use of energy from renewable sources (REDII), Article 27(3), requests the Commission to adopt a delegated act by December 2021 on how to document that the used electricity is of renewable origin and leads to emissions reductions, while recital 90 provides direction for the conditions.

Without prejudging these upcoming REDII rules, the applicant should submit a planning for the procurement of fully renewable electricity (e.g. through a Renewable Power Purchase Agreement with a provider in the same regional market). At financial close or before the start of operations, the applicant has to submit the contracts and documentation. For further details see Appendix A1.5.

2.2.3.1 RIGID inputs

As the GHG emission calculations take account of processes which divert materials from other uses, it is necessary to consider whether an input is “rigid”.

If the input has a fixed supply, then it is considered “rigid”; it can only be supplied to a new project by diverting it from another use. Its emissions intensity then considers the impact of diverting it from its existing use. The emissions intensity may be negative (i.e. avoidance of GHG emission) if the input was releasing emissions in its existing use, or positive (creating GHG emissions) if it was avoidance emissions in its existing use. The exact definition of a rigid input is given in the Appendix A1.2.

Examples of rigid inputs include:

- municipal waste, used plastics, used lubricating oil;
- intermediate streams from existing processes: e.g. blast furnace gas, black liquor;
- process heat or waste heat taken from an existing process; and
- economically minor by-products of existing processes, where the ratio of the outputs cannot be changed significantly. (to determine what are minor by-products see Appendix A1.2). An example of this type of rigid input is hydrogen recovered from an existing chlor-alkali process, which was already being sold as an industrial gas.

The emissions implications of the use of rigid inputs follow from considering the emissions in the project and reference scenarios, with all functions and products balanced:

Example: municipal waste as an input

The emissions intensity takes into account the existing fate of the waste, as well as the emissions associated with any additional treatment and transport. For example, if its existing fate was incineration without energy recovery, the emissions from the incineration are avoided, and this means the emissions attributed to using the waste are negative, i.e. avoiding the original fate saves emissions, so there is a CO2 credit for its novel use. If it is diverted from landfill, the carbon emissions attributed to it at the point of collection will also be negative. These shall be assumed equal to those
for incineration without energy recovery, because although landfill sequesters part of the carbon, it is not desirable to encourage landfill for other environmental reasons.

But if for example, a “waste” input is diverted from being burnt to provide district heating, the emissions avoided by the burning of the waste for district heating are offset by the additional emissions incurred by replacing that district heat, for example by using a natural gas boiler.

**Example: “waste heat” as an input**

A process may take heat from another existing process outside the control of the applicant. In this case, the emissions attributed to the heat input shall be the increase in the emissions of the other process associated with the heat export. Thus, if the heat is truly “waste heat”, it would be considered free of emissions. On the other hand, if extra fuel needs to be burnt to replace the heat in the existing process, its emissions intensity is the emissions from burning that extra fuel. Where heat is provided by an industrial heat network from multiple other plants, the emissions intensity of that heat can be taken as the same as that used in EU ETS declarations.

**Example: industrial off-gas as an input**

For example, if a stream of industrial off-gas is diverted from flaring with release of the CO2 to the atmosphere, the emission attributed to that input is negative; equal in magnitude to the CO2 release that is avoided.

If the industrial off-gas produces process heat in the reference scenario, the applicant should estimate the emissions from the source of heat that replaces the heat lost by diverting the gas its use in the project, and add these to the project scenario.

As emissions for electricity are set to zero there is no emissions penalty in the Innovation Fund for diverting gases from electricity production.

**Application of the Waste Framework Directive**

Projects that involve the use of “waste” materials must respect the current version of the Waste Framework Directive. The waste hierarchy in the Waste Framework Directive puts top priority on mechanical recycling (e.g. recycling used plastic as plastic). Converting waste to a fuel is specifically excluded from the definition of “recycling” in the Waste Framework Directive, and does not count towards recycling targets for Member States: it is classed as “recovery”, on a lower level of the waste hierarchy, along with burning it for electricity and/or heat production,

Therefore projects that use, as feedstock, materials covered in the Waste Framework Directive, such as used plastics, must precisely define the “waste” they are intending to use, and justify why it cannot be given a higher-priority treatment under the Waste Framework Directive, during the lifetime of the project. Furthermore, the alternative treatment of the feedstock assumed in the reference scenario must be at the highest level possible for that quality of waste in the waste hierarchy of the Waste Framework Directive.

---

9 Directive 2008/98/EC on waste and its amendments
2.2.3.2 **ELASTIC inputs**

If the supply of the input varies in order to meet the change in the demand, then the input is considered “elastic”, and its emission factor is found from the emissions involved in supplying the extra input. The exact definition of an elastic input is given in the Appendix A1.2.

According to section 2.2.3.1, the emissions intensity of a rigid input may be based on the elastic input that replaces it in its existing use. The provisions in this section also apply to those elastic inputs: they are considered on the same basis as the other elastic inputs that change between project and reference scenarios.

**Minor elastic input changes**

At each stage of the project application, the applicant should make a list of all elastic inputs that change between project and reference scenarios.

- **At the first stage of application**, the applicant may select from this list, “minor”, elastic inputs whose emissions jointly amount to less than 30% of the total emission avoidance of the project. A preliminary calculation may need to be done with the reference emissions, in order to determine whether the thresholds are breached.

- **At the second stage and monitoring and reporting for disbursements**, the selection of minor elastic inputs must be restricted so that their emissions jointly amount to less than 15% of total of the total emission avoidance of the project.

- **For monitoring and reporting for knowledge-sharing**, the selection of minor elastic inputs must be restricted so that their emissions jointly amount to less than 10% of total of the total emission avoidance of the project.

The emissions associated with the selected minor elastic inputs may be derived from reference literature, according to the method and hierarchy in the Appendix A1.3.

**De Minimis inputs**

At the first stage of application, the applicant may select from the list of inputs *de minimis inputs*, whose emissions jointly amount to less than 10% of the total emission avoidance of the project. A preliminary calculation has to be done with the reference emissions, in order to determine whether the thresholds are breached.

At the second stage and for monitoring and reporting for disbursements, the selection of *de minimis inputs* must be restricted so that they jointly amount to less than 5% of total of the total emission avoidance of the project.

For monitoring and reporting for knowledge-sharing, the selection of *de minimis inputs* must be restricted so that they jointly amount to less than 2% of total of the total emission avoidance of the project.

The emissions of *de minimis inputs* may be neglected. *De minimis inputs* do not count as minor elastic inputs in calculating the joint emissions of the minor elastic inputs.

Inputs that do not fall under the definition of “minor”, or *De minimis* are “major”.

**Fossil Fuels Inputs (major and minor)**

The carbon content for inputs of fossil fuels appears either in the process emissions (for the part that is combusted) or in the combustion emissions of the product. Consistent with the ETS-based accounting of changes in process emissions, as long as the ETS-based accounting of emissions is performed (by carbon mass-balance and/or direct measurement) no separate accounting of fossil fuel inputs is needed.
Biomass, biogas, bioliquid and biofuels inputs (major and minor)

Biomass, biogas or biofuels used in IF projects must conform to the sustainability requirements of the REDII.

If they come from a known supply source, which declares “actual emissions” under the REDII those declared emissions for the biofuel may be assumed for that input in the present calculation, but diminished by 15% since the REDII takes into account a wider range of emissions, notably emissions from the production steps of the fossil fuel supplied to the biomass processing.

Otherwise, the emissions factor for biomass, biogas, biomethane, bioliquid or biofuels from an indeterminate supplier, are the default emissions tabulated in Annex V and VI of REDII, diminished by 15%.

These rules apply for all stages of the application, but save administrative burden since suppliers will probably already be declaring emissions under REDII.

Remember that the CO2 emissions from the combustion of bio-based carbon are not counted in the process(es) step.

Major elastic inputs from known new or expanded sources

If an input comes from a new plant or source set up for the purpose, but which is not under control of the applicant, that plant must if possible be incorporated in the project scenario. The same applies if a particular plant is expressly expanded to fulfil the increased demand for the project, (in which case of course the unmodified plant will then go into the reference scenario).

If input data is not available for the new or expanding supply plant, the emissions factor of the input shall be calculated as for an input from indeterminate source.

Minor elastic inputs, and major elastic inputs from indeterminate sources

The main elastic inputs from indeterminate sources are expected to be fossil fuels. However, combustion emissions from fossil fuel inputs are already considered in the EU ETS-based accounting of the process step, and that accounts for most of the total emissions intensity of fossil fuels. To avoid complications, the other components of the complete emissions intensity shall be ignored, so that no emissions other than the combustion emissions shall be considered for inputs of fossil fuels. In this connection, “fossil fuels” comprise natural gas, coal, petroleum coke, bitumen, all grades of fuel oil, diesel, gasoline, kerosene, naphtha, LPG, and refinery gas. The combustion emissions factor for some of the more commonly-used fuels are tabulated in Error! Reference source not found.Error! Reference source not found.

Other inputs, such as high value chemicals, may have much higher processing emissions than simple fuels. However, life cycle and well-to-wheel databases show total carbon intensity, which is the sum of the stoichiometric carbon content and all emissions from processes in the supply chain. For inputs that do not contain carbon, there is no difference, but for carbon-containing inputs, the appropriate emission factors can be found by subtracting from the carbon intensity the stoichiometric carbon content of the input converted to mass of CO2 using the molar weight ratio 44/12. The required data is taken from the reference literature according to the method and hierarchy in section A1.3.

Attribution of emissions between co-products in the supply of elastic inputs

If a major elastic input is one of multiple co-products, it is necessary to share process-stage emissions between the co-products. For a rigid input the calculation of emissions intensity
may be based on the elastic product that replaces it in its existing use, so the attribution may be needed there too.

For the purposes of the calculation of attribution of emissions to co-products, the emissions to be shared shall be all the considered emissions that take place up to and including the process step at which the co-products are produced. Obviously, if an input to the process is itself a co-product of another process, the sharing out of emissions at the other process must be done first to establish the emissions to be attributed to the input.

ISO 14044 (2006) provides a framework for such an attribution and for calculating the emissions intensities for the supply of elastic inputs that are co-products of another process as illustrated in Appendix A1.1.

In the flow chart “allocation by physical causality” at the second level requires analysis showing the emissions consequences of changing the output of the product without changing the output of co-products, and will often require process modelling.

At the third level, allocation shall generally be made by the economic value of the co-products. Any other choice needs to be clearly justified in terms of how the chosen allocation key describes the “cause of the limit” of production.

### 2.2.3.3 Electricity inputs supplied to industrial projects

No emissions shall be ascribed to electricity either consumed or exported in a project. However, for knowledge-sharing purposes, the actual change in electricity consumption or export between the project and reference scenarios shall be reported. The project should also report whether the timing of the consumption or export is correlated with the time-varying emissions of the grid, and in this case hourly electricity consumptions shall be reported for the reporting period.

### 2.2.3.4 Lowering grid electricity emissions by timing plant operation

Even without any certification or contracts to use additional renewable electricity, a plant using electricity (such as an electrolyser) can reduce the emissions of its electricity supply by operating only at times when the emissions of the electricity supply are below average. This demand management will become more important in the future as the grid accommodates increasing fractions of intermittent wind and solar electricity. It helps grid stability in the same way as electricity storage.

To estimate the electricity emissions in this mode of usage, the applicant resolves the time-dependent electricity demand into a storage component plus a constant average consumption, as indicated in the diagram below. The emission avoidance of the virtual storage component shall be calculated as in section on emissions accounting for energy storage (see Section 5).
2.2.4 $\Delta E_{\text{products}}$

If a project does not change the products (or functions) of the process, no calculation is required. If the products (or functions) are changed, applicants must calculate the emissions saved (or incurred).

The processes in the project and reference scenarios should balance the principal products; however, there may be inevitable changes in by-products. To balance the scenarios, the emissions attached to changes in by-products must be considered. By-products produced in the project scenario but not in the reference scenario increase the project’s emission avoidance by the emissions attributed them; conversely by-products products produced in the reference scenario but not in the project scenario increase the project’s emission avoidance by the emissions attributed them. The emissions factors needed for this calculation are calculated according to the method in the paragraph on *Minor elastic inputs, and major elastic inputs from indeterminate sources* in section 2.2.3.2.

2.2.5 $\Delta E_{\text{use}}$

Innovative products may save emissions in the use phase by increasing energy efficiency or reducing emissions during use. For example, new agrochemicals could reduce nitrous oxide emissions when used on the soil; innovative absorbents or catalysts could save emissions in the chemical industry.

The emission avoidance in use are first estimated per tonne of product. Then the scale of production assumed in the calculation of total emission avoidance is limited to the quantity that the applicant is confident to be able to sell. During monitoring and reporting stage, applicants will be required to prove the amount of products sold in addition to monitoring and reporting of the parameters related to the production of the product.
2.2.6 $\Delta E_{\text{end of life}}$

Most projects will not change end-of-life emissions of the products. However, effects on the life-cycle emissions are possible. For example, innovative refrigerants could replace others with higher global warming potential, avoidance emissions when they leak or are not collected at end-of-life. Furthermore, some projects may propose more efficient recycling due to changes in products. Therefore in such cases, changes in end-of-life emissions may be estimated and added to the emissions changes from other project stages.

2.3 Relative emission avoidance for industrial projects

Applicants have to estimate a comparative indicator for the percentage reduction in emissions. For the general formula, please look at section 1.1.3. In case of multiple products, the relative emission avoidance for the product(s) for which the applicant is claiming funding (principal product(s)) is found by dividing the emission avoidance of the project, by an estimate of the emissions for the production of the chosen “principal product(s)” in the reference scenario.

If there are products in the reference scenario apart from the “principal products”, the total emissions in the reference scenario must be shared between the “principal products” and the others, using the attribution procedure in Appendix A1.1.

2.4 Data and parameters

Each project will present the parameters that will be deemed as constant throughout the duration of the project and, consequently, shall not be monitored choosing the sources of data as explained above. These will include all emission factors, combustion emissions (carbon contents) and lower heating values (net calorific values) after approval at second stage.

2.5 Monitoring, reporting and verification of performance for disbursement and knowledge-sharing

A monitoring plan consisting of a detailed, complete and transparent documentation of the parameters used in calculations and data sources shall be submitted by the applicant. For each stage of the application, the documentation should include the following elements:

- Process diagrams for the “project”, “reference” and “change” scenarios, filling out Figure 2.1 by indicating all the sub-processes, inputs, and products that will be changed by the project, either in terms of technology or output (“activity level”).
- A simplified process diagram for the three scenarios showing only the main sub-processes and flows important to the emissions-avoidance calculations.
- Explanation of the choices in the reference scenario, as described in section 2.2.2.1
- A list or diagram quantifying all the material and energy flows between the sub-processes in the project and reference scenarios.
- A list quantifying each of the products (or functions) delivered by the “processes” stage of in the three scenarios.
- Identification of the selected “principal product(s)” (or functions) from the list of products for the project scenario.
- Lists quantifying each material and energy input entering the “process(es)” stage of each scenario, organized in decreasing order of size. At the bottom of the list, descriptions may be generic (e.g. “other process chemicals”, “lubricants”).

[ICF, Fraunhofer, milieu, TURQUOISE logos]
- From the list of inputs for the “change” scenario, identification of “de minimis” and “minor inputs” following section 2.2.3.2.
- List of the emissions intensities taken from the literature according to section 2.2.3.2, 2.2.2.2 and 2.2.4 and the sources of the data.
- A documented calculation of the absolute and relative emission avoidance from the project.

At the reporting stage, all measurements should be conducted with calibrated measurement equipment according to relevant EU ETS MRR requirements.

Monitoring is not necessary for the inputs of biological origin, since either REDII default emissions factors are used, or the actual values which are checked under the monitoring provisions of REDII. It is enough to document the provenance of the batches of inputs of biological origin.

In addition to the parameters listed above, the following parameters will be monitored and reported for knowledge sharing purposes for projects using grid electricity where applicable:

- Hourly profiles for use and feed-in of grid electricity.
- Hourly profiles for generation of electricity delivered to the project from PPAs.
- Hourly profiles for avoided curtailment based on final physical notifications of co-located RES plants or grid operator instructions.
- Lessons learned and experiences.

The detailed knowledge-sharing requirements are spelled out in the Model Grant Agreement, call text and knowledge-sharing plan template.
A1.1 Attribution of emissions to co-products in emissions calculations for IF projects

A simplified version of the ISO 14044 (2006) multifunctionality framework is used to attribute emissions to co-products.

Figure A1.1 Simplification of the ISO 14044 (2006) hierarchy for sharing emissions between co-products\(^{10}\)

Following the diagram, the applicant first sees if any installation inside the project boundary treats only one of the project’s co-products: then obviously the emissions from that installation can be ascribed entirely to that co-product.

If that does not completely solve the problem, the next question is whether the process allows one to change the ratio of the co-products produced (as is possible, for example in a “complex” oil refinery) or whether the ratio is fixed, for example by the stoichiometry of a chemical reaction. If the ratio of outputs is variable, allocation of emissions between products is made, if possible, by “physical causality” (level 2 of the ISO hierarchy): calculating the effect on the process’ emissions of incrementing the output of just one product whilst keeping the other outputs constant. This is \textit{not} the same as allocating using an arbitrary physical property of the products.

If it is impossible to make the incremental calculation just described, or if the ratio of the products, is fixed, the 3\(^{rd}\) level of the hierarchy is invoked. In an industrial process, the motivation for making different products is the market value of the products. So, at this 3\(^{rd}\) level, allocation by the economic value\(^{11}\) of the products is the preferred choice. Allocation by other properties, such as weight or volume, of the different products may only be done where it can be shown that they are the “cause of the limit” of the function.

The point in the supply chain where the allocation is applied shall be at the output of the process that produces the co-products. The emissions allocated shall include the emissions from the process itself, as well as the emissions attributed to inputs to the process.

\(^{10}\) The option in ISO 1044 (2006) to “enlarge the system boundaries to include all the co-functions” does not exist in this case, because we must find the emissions attributable to the “principal product(s)”, which are already fixed. Also the option in ISO 1044 (2006) to apply substitution to by-products has been eliminated in order to simplify calculations. Note: LP: linear programming, FU: functional unit.

\(^{11}\) The average price over the previous 3 years should be used; any other assumption must be justified. Objections that “the price varies” will not be considered: it is better to have a method that is approximately correct than one which is exactly wrong.
A1.2 Processes with a fixed ratio of outputs: definition of rigid, elastic and semi-elastic products

Some inputs may be products of processes that produce a fixed ratio of outputs. Consider a process that produces various outputs (products, by-products, residues or wastes) in fixed ratios and with different prices. If the incentive for a company to increase the production of the whole plant is proportional to the sum of the economic value of all the outputs; the fraction of the incentive from one output is proportional to its value-fraction in the total value of products produced by the plant.

For example, if one output is a waste with zero value, its value-fraction is zero and there is no incentive to increase overall production to supply more of it. This means the waste has a rigid supply. At the opposite extreme, if the process only has one output, then it represents the entire incentive to increase production, so the supply of that output will increase with demand, its supply is perfectly elastic.

In order to reduce the administrative burden of the calculation for products that are in between these extremes, the following simplification is applied:

- A product that represents less than 10% of the value of the total products of the supplier are treated as perfectly rigid, and their emissions calculated accordingly.
- A product that represents more than 50% of the total value of the products of the supplier are treated as perfectly elastic, and their emissions calculated accordingly.
- The emissions attributed to a product that represent between 10% and 50% of the total value of the products of the production process shall be:

\[
\frac{(\text{emissions assuming elastic source}) \times (VF - 0.1) + (\text{emissions assuming rigid source}) \times (0.5 - VF) }{(0.5 - 0.1)}
\]

\[\cdots \text{where } VF = \text{Value Fraction of the product} = \frac{(value \text{ of the product})}{(total \text{ value of all the products produced by the process})}\]

This relation is represented in the following graph. This graph is only schematic; the emissions calculated assuming the result is elastic are not necessarily higher than those assuming that it is rigid, and calculated emissions can also be negative.

In calculating VF, the prices should be the average of the data for the last 3 years.
In practice, we it is expected that the great majority of inputs to fall into either the “elastic or “rigid category, so the simplification is considerable in most cases. The prices should be the average of the data for the last 3 years.

An example of such a process is the chlor-alkali process, which produces sodium hydroxide, chlorine and hydrogen in a ratio that is fixed by stoichiometry. Here, we consider the case where all three are sold as inputs to a process in IF. By contrast, if the hydrogen is not sold, but is being burnt for process heat, then the emissions of the plant are obviously only attributed to sodium hydroxide and chlorine. If it is then proposed to start selling the hydrogen, replacing the process heat with natural gas, the hydrogen is a rigid source, and its emissions are given by those of the natural gas that replaces it.

A1.3 Hierarchy of data sources for inputs and products in industrial projects

The GHG emissions intensity and combustion emissions of inputs or products, that is not specified elsewhere in the section on industrial projects, and need to be found from literature (which never includes heat or electricity), will be taken from the following sources, in order of preference (top to bottom). Note that the emissions intensity is not the same as combustion emissions (which are used for calculating the direct carbon emissions for processes in EU ETS). Emissions intensity is also known, for transport fuels, as well-to-wheels emissions: it comprises not only combustion emissions, but also all the emissions from the supply chain: extraction of raw materials, all steps in the processing, transport and distribution.

1. Stoichiometric combustion emissions for a wide range of fuels is provided in IPCC 2006 Guidelines for National Greenhouse Gas Inventories.
2. Emissions intensity for most widely-used process chemicals are provided in “Definition of input data to assess GHG default emissions from biofuels in EU legislation”. (European Commission 2016)\textsuperscript{12}. The same values are intended to be

shown also in a revised version of the BIOGRACE tool\textsuperscript{13}. These data are already used for calculating emissions for biomass, bio-liquids and biofuels in Annex V of REDII. However, these data include a wider range of emissions than those in EU ETS, and the rest of the present calculations; in particular they include both upstream emissions for the provision of fossil fuels, emissions for transport and distribution of products, and the combustion emissions of any fuel products. Therefore, to obtain values that are approximately coherent with the emissions calculated in EU ETS from combustion of fossil fuels, first 15\% is subtracted from all the values to account for the upstream (etc.) emissions.

3. If the data are not available there, coherent data for a different range of inputs/products may be found in JEC-WTW v.4, WTT appendix 4, which shares the same input database as the calculations in annex V of REDII.

4. Calculations using input data from ECOINVENT 3.5. Calculations in ECOINVENT should use the “cut-off system model”. An equivalent calculation may also be made in proprietary software packages (e.g. GABI, openLCA) using the same input data. If the emissions calculations cannot be made without considering upstream emissions for fossil fuel supply, an approximate adjustment to the complete lifecycle emissions should be made by subtracting 15\% from the emissions intensity result. If the calculation calls for allocation of emissions between multiple products, allocation by economic allocation should be selected (the database includes the cost of products).

5. “Official” sources, such as IPCC*, IEA* or governments (but note that most IPCC and IEA tables show combustion emissions, not emissions intensity).

6. Other reviewed sources of data, such as E3 database, GEMIS database.

7. Peer-reviewed publications.

8. Duly documented own-estimates.

9. “Grey literature”: unreviewed sources, such as commercial literature and websites.

\textsuperscript{13} www.biograce.net/
3 Carbon Capture and Storage

Carbon capture and storage (CCS) projects are characterised by the capture of exhaust gases in large industrial processes or power generation, followed by a separation and compression of the CO₂, which will then be transported by road tankers, ships, rail and/or pipelines to a suitable storage site where it will be injected and permanently stored in a storage site permitted under Directive 2009/31/EC, such as depleted oil and gas reservoirs, un-mineable coal beds, saline aquifers, or basalts. Applications for such projects can be submitted by any players in the CCS supply chain, i.e. by the legal entity hosting the capture installation, or by legal entities providing transport services or injection infrastructure. If the full CCS supply chain is not part of the application, the applicant should demonstrate the provision of the remaining services in the CCS supply chain by third parties. As 60% of the IF grant is dependent on verified emission reductions, if CO₂ capture and or CO₂ transport projects are submitted for funding, then when they report during operation, they will have to prove that amount of CO₂ they claim is stored in a site permitted under Directive 2009/31/EC.

Building on the reporting requirements for EU ETS, the GHG emission avoidance for CCS projects will be calculated by deducting project emissions (i.e. emissions that are only occurring due to the project activity) from the reference emissions that would occur in the absence of the project, which is represented by the amount of CO₂ transferred to the capture installation.

Project emissions from the CO₂ capture activity using pre-, post-, oxyfuel or chemical looping combustion techniques, the injection in the geological storage site and the transport network of CO₂ by pipelines shall be quantified according to Article 21, 22 and 23 of Annex IV of Commission Implementing Regulation (EU) 2018/2066 of 19 December 2018. Project emissions due to transportation by road and maritime modals shall be quantified based on distance travelled data, type of modal and load. This methodology assumes the transportation of the CO₂ will be done through heavy goods vehicle (HGV) when via road, and by sea tankers in the maritime journeys.

Successful projects will be required to maintain records of measurements, quality assurance and quality control procedures and calculations used in the development of data reported, along with copies of reported data and forms submitted.

3.1 Scope

This methodology applies to project activities that involve capturing and compressing of CO₂ from power and heat generation facilities or energy-intensive industries, including oil refineries, steel works and production of iron, aluminium, metals, cement, lime, glass, ceramics, pulp, paper, cardboard, acids and bulk organic chemicals, for injection in a storage site permitted under Directive 2009/31/EC on the geological storage of carbon dioxide.

This methodology is applicable to CCS project activities such as but not exclusive to:

3.1.1 Plant of Origin
- Energy-intensive industries,
- Fossil fuel power generation facilities,
- Natural gas processing.

3.1.2 Technologies
- Pre-combustion,
- Post-combustion,
- Oxyfuel combustion,
- Chemical looping combustion.

3.1.3 Storage sites
- Depleted (or nearly depleted) oil and gas reservoirs,
- Unmineable coal beds,
- Saline aquifers,
- Basalts.

3.2 Project boundary
The greenhouse gases and emission sources included in or excluded from the project boundary are shown in Table 3.1.

3.3 Absolute GHG emission avoidance
The equation to be applied in both first and second stages for the calculation of absolute GHG emission avoidance is described in the following.

$$\Delta \text{GHG}_{\text{abs,CCS}} = \sum_{y=1}^{n} \text{Ref release,}_y = \sum_{y=1}^{n} \text{CO}_2\text{transferred to the capture} - \sum_{y=1}^{n} (\text{Proj capture,}_y + \text{Proj transport pipeline,}_y + \text{Proj transport road,}_y + \text{Proj transport maritime,}_y + [3.1]$$
<table>
<thead>
<tr>
<th>GHG emission avoidance</th>
<th>= Reference scenario emissions - Project emissions</th>

</thead>
<tbody>
<tr>
<td>installation, y</td>
<td>Projinjection, y</td>
</tr>
</tbody>
</table>

Where:

\( \Delta \text{GHG}_{\text{abs,CCS}} \) = Absolute GHG emissions avoided by the CCS project, in tonnes CO\(_2\)e.

\( \text{CO}_2 \) transferred to the capture installation, \( y \) = Amount of CO\(_2\) transferred to the capture installation in year \( y \), in tonnes CO\(_2\)e, determined in accordance with Commission Implementing Regulation (EU) 2018/2066 on the monitoring and reporting of greenhouse gas emissions pursuant to Directive 2003/87/EC of the European Parliament and of the Council and amending Commission Regulation (EU) No 601/2012, especially Articles 40 to 46 and Article 49 and Annex IV, Section 21, 22 and 23.

\( \text{Proj}_{\text{capture}, y} \) = GHG emissions from CO\(_2\) capture activities for the purposes of transport and geological storage in a storage site permitted under Directive 2009/31/EC in year \( y \), in tonnes CO\(_2\)e. This includes emissions from fuel and input material use for compression and liquefaction of the CO\(_2\), as well as fugitive and venting pre-injection. It shall be calculated according to Regulation (EU) 2018/2066, Annex IV, Section 21.

\( \text{Proj}_{\text{transport pipeline}, y} \) = GHG emissions from transport of CO\(_2\) by pipelines for geological storage in a storage site permitted under Directive 2009/31/EC in year \( y \), in tonnes CO\(_2\)e. This includes emissions from combustion and other processes at installations functionally connected to the transport network including booster stations; fugitive emissions from the transport network; vented emissions from the transport network; and emissions from leakage incidents in the transport network. It shall be calculated according to Regulation (EU) 2018/2066, Annex IV, Section 22.

\( \text{Proj}_{\text{injection}, y} \) = GHG emissions from geological storage of CO\(_2\) in a storage site permitted under Directive 2009/31/EC in year \( y \), in tonnes CO\(_2\)e. This includes emissions from fuel use by associated booster stations and other combustion activities including on-site power plants; venting from injection or enhanced hydrocarbon recovery operations; fugitive emissions from injection; breakthrough CO\(_2\) from enhanced hydrocarbon recovery operations; and leakages. It shall be calculated according to Regulation (EU) 2018/2066, Annex IV, Section 23.

\( \text{Proj}_{\text{transport road}, y} \) = GHG emissions due to the transportation of CO\(_2\) in tank trucks or other road modal in year \( y \), to be calculated according to Equation [3.2], in tonnes CO\(_2\)e.

\( \text{Proj}_{\text{transport maritime}, y} \) = GHG emissions due to the transportation of CO\(_2\) in sea tankers or other maritime modal in year \( y \), to be calculated according to Equation [3.2], in tonnes CO\(_2\)e.

\( y = \) first year of the operation

\( n = 10^{th} \) year following the start of operation

3.5 Monitoring, reporting and verification of performance for disbursement and knowledge-sharing

A monitoring plan consisting of a detailed, complete and transparent documentation of the parameters used in calculations and data sources shall be submitted by the applicant at second stage of application. This document shall contain at least the elements laid down in Equations [3.1] and [3.2].

Table 3.4 Parameters for monitoring

presents the parameters that, at minimum, shall be monitored throughout the project and be part of the project’s monitoring and reporting plan to be submitted.

For the parameters for monitoring corresponding to the Proj\text{capture}, Proj\text{transport pipeline} and Proj\text{injection}, please refer to the Monitoring and Reporting Regulation, especially Articles 40 to 46 and Article 49 and Annex IV, Sections 21, 22 and 23. For estimating such emissions, the applicant may also consider the adoption of standard ratios in GHG emissions per tonne of CO₂ stored based on industry benchmarks, should these be available.
All measurements should be conducted with calibrated measurement equipment according to relevant industry standards.

For carbon capture and storage projects, there will not be a difference in the MRV for disbursement and for knowledge-sharing.

</table>
In addition to the parameters listed above, it is suggested that the following parameters are monitored on a yearly basis and reported for **knowledge sharing purposes**. Substantial monthly deviations if any should also be reported.

- Capture ratio, in tonnes CO2e emitted / tonne CO2 fossil transferred to the capture installation.
- Transport by pipeline ratio, in tonnes CO2e / tonne CO2 fossil transferred to the capture installation.
- Injection ratio, in tonnes CO2e emitted / tonne CO2 fossil transferred to the capture installation.
- Type(s) of modal(s) used in the transportation of the CO2 from the site of origin to the storage site.
- Weight fraction of the truck, train wagon or ship occupied by the compressed CO2 and, separately, the empty tank (i.e. fully or partially loaded), per trip and modal.
- High-level mapping of environmental impacts and mitigation measures.
- High-level risk screening and mitigation measures.
- Lessons learned and experiences.

The detailed knowledge-sharing requirements are spelled out in the Model Grant Agreement, call text and knowledge-sharing plan template.
4 Renewable energy

This section describes the calculation of GHG emission avoidance from innovative renewable energy projects such as bioelectricity, bio-heat, solar, geothermal, wind, and hydro/ocean energy. Emission avoidance from projects whose principal products are biofuel or biomaterials for use in bio-refineries, are more complex to calculate, necessitating the use of the rules in Section 2, based on the procedures for industrial projects.

The emissions of the project are defined by the difference between the main emissions from the project activity, and the emissions that would occur in the absence of the project for the generation or use of the same amount of energy using the conventional technology or fuel.

For the sake of simplification and to enable a fair competition between projects, the reference scenario has been pre-defined for all projects producing the same output, despite the regional differences that will invariably be observed in real life. Therefore, for the purpose of the IF, if the output is grid-connected electricity, the emissions attributed to grid electricity in the reference scenario corresponds to the typical EU grid emissions during in 2030 according to the Commission’s PRIMES/EUCO3232.5 scenarios. For all projects generating renewable heating, a natural gas boiler with 90% LHV efficiency shall be adopted as the reference scenario.

Applicants for projects generating more than one energy output, e.g. heat and electricity, biofuel and heat, etc., shall calculate the GHG emission avoidance separately using the appropriate equation for each energy output and add them up.

In terms of the project emissions, sources of GHG emissions depend on the technology and supporting infrastructure for the operation of the plant. Normally, emissions from wind, solar and ocean energy generation are relatively minor. However, the same is not true for other renewables, such as geothermal, waste to energy, where emissions could include, for instance, fuel combustion in the plant and in on-site machinery, as well as fugitive losses.

Therefore, for the purpose of the IF, the applicant shall quantify at a minimum the emissions from all the direct sources (Scope 1), indirect emissions from the generation of purchased electricity and/or steam (Scope 2) and other indirect emissions that occur across the value chain (Scope 3), as per definition of the GHG Protocol Corporate Standard. Although this approach does not require the quantification of all cradle-to-grave emissions, it intends to capture the main emissions sources within the project boundaries and control.

For projects that include storage of renewable electricity at times when there is an excess of it in the grid-mix, e.g. smart grid applications, please refer Section 2.2.3.4, for guidance on the methodology and emission factors to apply.

Funding could be used for the retrofitting (or repowering), rehabilitation (or refurbishment), replacement or capacity addition of an existing renewable power plant, the construction of a power plant that will use renewable energy sources to generate energy; or the construction of a manufacturing plant of components of innovative technologies that will generate renewable energy, when implemented.

Successful projects will be required to maintain records of measurements, quality assurance and quality control procedures and calculations used in the development of data reported, along with copies of reported data and forms submitted.

---

14 The GHG Protocol Corporate Standard classifies a company’s GHG emissions into three ‘scopes’. Scope 1 emissions are direct emissions from owned or controlled sources (e.g. fuel combustion on site such as in boilers, fleet vehicles and air-conditioning leaks). Scope 2 emissions are indirect emissions from the generation of energy purchased and used by the organisation. Scope 3 emissions are all other indirect emissions that occur across the value chain of the organisation, in sources that the organisation does not own or control, such as business travel, raw material production, waste degradation.
4.1 Scope

This methodology applies for innovative renewable energy projects for the purpose of generating grid-connected electricity and heating/cooling, including electricity and/or heat produced from biomass or fuels derived from biomass.

Any innovative renewable energy generation projects that can demonstrate GHG emission avoidance could be eligible for funding.

This methodology envisages applications from activities that meet the conditions listed below.

4.1.1 Products

- Grid-connected electricity from wind, solar, ocean, hydro, geothermal energy, biomass
- Combined heating and power from geothermal energy or biomass
- Heating and cooling, including from solar and geothermal energy, biomass
- Components for renewable energy installations (e.g. production of innovative heat pumps, PV modules and wind turbines)

4.1.2 Possible types of projects

- Retrofitting (or repowering), rehabilitation (or refurbishment), replacement or capacity addition of an existing renewable power plant.
- Construction of a power plant that will use renewable energy sources to generate electrical and thermal energy; or
- Construction of a manufacturing plant of components of innovative renewable technologies

For the situations where funding will be used to finance the construction of a manufacturing plant of innovative technologies' components, applicants shall demonstrate the existence of a buyer (i.e. a company that will run the innovative technology to generate renewable electrical or thermal energy) to ensure that the intended GHG emission avoidance will be delivered. The GHG emission avoidance will be calculated and checked based on the number of components (planned to be) sold.

4.2 Project boundary

The emission sources that shall be included within the boundaries of the calculations for wind, ocean, solar, geothermal and bio-fuels\textsuperscript{15} to grid or to heat projects are shown in Table 4.1.

Table 4.1 Emission sources included in or excluded from the boundaries of the GHG emission avoidance calculation

\[ \text{EG}_{\text{heat},y} = P_{\text{heat}} \times \text{PLF} \times T_y \] \[4.6\]

Where:
\[
\begin{align*}
\text{EG}_{\text{grid},y} &= \text{Net amount of electricity to be generated by the renewable technology and fed into the grid in year } y, \text{ in MWh. Calculated according to Equation [4.4].} \\
\text{EG}_{\text{heat},y} &= \text{Net amount of thermal energy to be delivered by the renewable technology in year } y, \text{ in MWh. Calculated according to Equation [4.6].} \\
P_{\text{elec}} &= \text{Electric power plant installed capacity, i.e. maximum electrical power output, in Watts.} \\
P_{\text{heat}} &= \text{Heating/Cooling generation plant installed capacity, i.e. maximum thermal power output, in Watts.} \\
\text{PLF} &= \text{Plant Load Factor, i.e. plant's capacity utilisation, in \%} \\
T_y &= \text{operating hours in year } y, \text{ in hours.} \\
\text{EF}_{\text{grid,ref}} &= \text{EU grid emissions factor in the reference period, in tonnes CO}_2e/\text{MWh. The appropriate EF presented in Table 4.4 should be applied.} \\
\text{EF}_{\text{NG}} &= \text{Emission factor due to the combustion of the reference fuel, in tonnes CO}_2e/\text{MWh. Assumed to be natural gas for all projects generating heat. The EF presented in Table 4.4 should be applied.} \\
y &= \text{year of operation}
\]

**Project emissions sub-equations**

\[
\text{Proj}_{\text{bio},y} = \sum_{y=1}^{n} \text{EC}_{\text{bio},t,y} \times \text{EF}_{\text{bio},t} \times 0.85^{17} \] \[4.7\]

Where:
\[
\begin{align*}
\text{EC}_{\text{bio},t,y} &= \text{Amount of bio-based fuel 'f' consumed by the project in year } y, \text{ in MJ (LHV).} \\
\text{EF}_{\text{bio},t} &= \text{GHG emissions from the supply of bio-based fuel 'f' used to make heat and/or electricity, produced, in tonnes CO}_2e/\text{MJ of bio-based fuel. Calculated according to Directive (EU) 2018/2001 of the European Parliament and of the Council of 11 December 2018 on the promotion of the use of energy from renewable sources (Recast), Annexes V and VI} \\
y &= \text{year of operation}
\]

For the situations where funding will be used to finance the **construction of a manufacturing plant of innovative technologies components**, \(\text{EG}_y\) shall be estimated based on the number of components produced each year, forecasted capacity for each component, the fractional emission avoidance due to the use of the component, as well as estimated load factor and operating hours, that the innovative technology(ies) or component(s) will be able to generate when implemented.

### 4.3.1.2 Second stage methodologies

<table>
<thead>
<tr>
<th>Project type</th>
<th>GHG emission avoidance</th>
<th>=</th>
<th>Reference emissions</th>
<th>-</th>
<th>Project emissions</th>
</tr>
</thead>
</table>

\[16\] For grid-connected electricity projects, only the energy generated and fed into the grid should be accounted for, i.e. any on-site losses or electricity generated for internal use shall be deducted. For the situations where the project involves retrofit/capacity added to an existing plant, only the surplus should be accounted for.

\[17\] To deducted emissions from the extraction and transport of crude oil, NG etc, as well as transport and distribution of the final fuel that are comprised in REDII but are not accounted for in EU ETS.
Delivered grid-connected electricity from wind, hydro, ocean, solar, geothermal energy and from biogenic sources. Including production facilities

\[ \Delta \text{GHG}_{\text{abs}, \text{RES to grid}, y} = \sum_{y=1}^{n} \text{Ref}_{\text{grid}, y} - \sum_{y=1}^{n} (\text{Proj}_{\text{on-site}} + \text{Proj}_{\text{geo}} + \text{Proj}_{\text{bio}, y}) \] [4.8]

Delivered heat from solar, geothermal energy and from biogenic sources. Including production facilities

\[ \Delta \text{GHG}_{\text{abs}, \text{RES to heat}, y} = \sum_{y=1}^{n} \text{Ref}_{\text{heat}, y} - \sum_{y=1}^{n} (\text{Proj}_{\text{on-site}} + \text{Proj}_{\text{geo}} + \text{Proj}_{\text{bio}, y}) \] [4.9]

Where:

\( \text{Ref}_{\text{grid}, y} \), GHG emissions for the generation of grid-connected electricity in fossil fuel fired power plants, which will be displaced due to the wind, solar, ocean and geothermal activity or from liquid, gaseous or solid biofuels in year \( y \), in tonnes CO\(_2\)e. Calculated according to Equation [4.3].

\( \text{Ref}_{\text{heat}, y} \) = GHG emissions for the generation of heating/cooling in fossil fuel fired plants, which will be displaced due to the wind, solar, ocean and geothermal activity or from liquid, gaseous or solid biofuels in year \( y \), in tonnes CO\(_2\)e. Calculated according to Equation [4.5].

\( \text{Proj}_{\text{on-site}, y} \) = GHG emissions due to fuel and electricity consumption at the project site in year \( y \), in tonnes CO\(_2\)e. Calculated according to Equation [4.10].

\( \text{Proj}_{\text{geo}, y} \) = GHG emissions from the operation of the geothermal power plant in year \( y \), in tonnes CO\(_2\)e. Calculated according to Equation [4.14].

\( \text{Proj}_{\text{bio}, y} \) = GHG emissions from the supply of biomass-based fuels for conversion into heat and electricity in year \( y \), in tonnes CO\(_2\)e. Calculated according to Equation [4.7].

\( y \) = first year of the operation

\( n \) = 10\(^{th}\) year following the start of operation

For the situations where funding will be used to finance the construction of a manufacturing plant of innovative technologies components, project emissions (Proj) shall be estimated based on the fractional emission avoidance due to the use of the component, the industry benchmarks and assumptions for the projected leakage emissions and fuel usage at the power plant, which will use the innovative technology(ies) or component(s), will consume when operating.

Reference emissions sub-equations

For the calculation of the emissions \( \text{Ref}_{\text{grid}, y} \), \( \text{Ref}_{\text{heat}, y} \), and \( \text{Proj}_{\text{bio}, y} \) please refer to the equations and sub-equations described in Section 4.3.1.1.

### Data / Parameter Description

- **EG<sub>grid</sub>**: Net amount of electricity to be generated by the renewable technology and fed into the grid.
  - Source: The net amount of electricity is to be informed by applicants.
  - Procedure: The data will be monitored by the applicants.
  - Frequency: The data will be monitored annually.
  - QA/QC Procedure: The data will be verified by applicants.
  - Responsibility for collection and archiving: The data will be collected and archived by the applicants.

- **EG<sub>heat</sub>**: Net amount of thermal energy to be generated by the renewable technology.
  - Source: The net amount of thermal energy is to be informed by applicants.
  - Procedure: The data will be monitored by the applicants.
  - Frequency: The data will be monitored annually.
  - QA/QC Procedure: The data will be verified by applicants.
  - Responsibility for collection and archiving: The data will be collected and archived by the applicants.

Alternativeness derived from: P<sub>elec</sub>, PLF, Ty for electricity, P<sub>heat</sub>, PLF, Ty for thermal energy.

When estimating leakage emissions for geothermal plants, the applicant may also consider the adoption of standard ratios for parameters like the mass of steam per MWh generated, steam losses and working fluid per tonne of steam, based on industry benchmarks, should these be available.

In addition to the parameters listed above, it is suggested that the following parameters are monitored and reported for knowledge sharing purposes:

- [All RES] Energy generated by hour, based on the actual load factor, and technology efficiency per operating hour.
- [All RES] Key raw materials and feedstock used at the power plant, and their origin.
- [Geothermal] Composition of steam by month, in % of each element.
- [Geothermal] Average loss, by month, i.e. Quantity of steam leaving the geothermal plant / Quantity of steam entering the geothermal plant, in %.
- [Geothermal] Average amount working fluid leaked/reinjected by month, in t working fluid/t steam entering the geothermal plant.
- [Geothermal] Heat production by month, in kWh / t steam entering the geothermal plant.
- [Geothermal] Electricity production by month, in kWh / t steam entering the geothermal plant.
- [Waste to energy] Original use/treatment of the feedstock.
- [Bioelectricity and heat] Type of bio-based fuel used (refer to annexes V and VI of the REDII). Any pre-treatment(s) of biomass before processing.
- [Bioelectricity and heat] Type(s) of modal(s) used in the transportation of solid biomass fuels from the site of origin to the bio-refinery or power plant.
- High-level mapping of environmental impacts and mitigation measures.
- High-level risk screening and mitigation measures.
- Lessons learned and experiences

The detailed knowledge-sharing requirements are spelled out in the Model Grant Agreement, call text and knowledge-sharing plan template.
5 Energy storage

GHG emission avoidance of an energy storage project is calculated as an annual comparison of the project emissions and the emissions in a reference scenario without the presence of an energy storage unit.

Specifically, emissions in the reference scenario will correspond to the emissions avoided due to the displaced energy by the output of the energy storage, whereas project emissions will be those associated with the input to the energy storage during operation.

If the services delivered by the project are useful from a system perspective, additional emissions associated with the input to the storage unit may be disregarded under certain conditions. In this respect, the methodology distinguishes various services that contribute to the GHG emission avoidance delivered by energy storage units, among others short-term electricity storage, auxiliary services to electricity grids, the avoidance of renewable energy curtailment, and longer-term energy storage. Stacking of services and multiple outputs are considered. The energy stored may both be sourced from an energy grid or directly from a plant and be delivered to an energy grid or directly to a plant. The applicant will be able to supply evidence for the origin and the user of the energy stored. Otherwise, default factors depending on the source and user will be applied. At first stage, on-site emissions of fugitive GHGs and from energy use other than energy storage can be omitted.

Successful projects will be required to maintain records of measurements, quality assurance and quality control procedures and calculations used in the development of data reported, along with copies of reported data and forms submitted.

During the operating period, the applicant will need to prove, based on the same annual methodology, that the GHG emission avoidance is delivered. In addition, the project operators will be asked to deliver hourly load profiles for knowledge sharing purposes.

5.1 Scope

This methodology applies to projects that include the construction and operation of a greenfield plant or the extension of an existing plant by a unit that stores any type of energy (in particular electricity, heat, cold, hydrogen, gaseous or liquid fuels) that was supplied to the moment of use. The storing of energy may include the conversion of one energy type into another.

A project is classified as an energy storage project, if energy storage (in any of the forms defined above) is the major purpose or one of its major purposes.

A project that includes energy storage but has as industrial production as a major purpose should follow the guidance for energy-intensive industry projects (see Section 2). For a project focusing on the production of hydrogen or renewable fuels of non-biological origin, the applicant should select to use this methodology if the majority of the revenue for the project comes from the energy stored (e.g. due to avoided curtailment). Otherwise, the applicant should follow the methodology for energy-intensive industry projects. If such a project or any other industrial project makes use of fluctuations in electricity markets, it should calculate the associated GHG emission avoidance based on the guidance for energy storage projects.

This methodology is applicable to energy storage projects related to the following services, technologies, energy sources and energy sinks (though not limited to the list below):

5.1.1 Services and products

- Short-term electricity storage (among others arbitrage, reserve power, ramping),
- Auxiliary services to electricity grids (among others reactive power, synchronous inertia),
- Avoidance of renewable energy curtailment,
- Other energy storage.
- Manufacture of components for energy storage, such as batteries

### 5.1.2 Technologies
- Electricity storage technologies,
- Heat and cold storage technologies,
- Hydrogen storage technologies,
- Gaseous fuel storage technologies, or
- Liquid fuel storage technologies.
- Combinations of the above, including smart grid technologies.

### 5.1.3 Energy sources
- Electricity grid
- Heat grid
- Gas grid
- Pipelines and trailers
- Renewable energy plants, or
- Waste heat recovery.

### 5.1.4 Energy sinks
- Electricity grid
- Heat grid
- Gas grid
- Pipelines and trailers,
- Fuelling stations, or
- Industrial plants.
5.2 Project boundary

The spatial extent of the project boundary includes the project energy storage plant/unit and all facilities that the IF project energy storage plant is connected to and are not metered separately.

The greenhouse gases and emission sources included in or excluded from the project boundary are shown in Table 5.1.

Table 5.1 Emission sources included in the project boundary

5.3 Absolute GHG emission avoidance

The equations to be applied in both the first and second stage are described in the following sections.

5.3.1 First stage methodologies

During the first stage of application, the absolute GHG emission avoidance by an energy storage plant shall be calculated according to Equation [5.1]. For a production facility that produces energy storage units, the absolute GHG emission avoidance shall be calculated according to Equation [5.2]. In the case of a production facility, the term ‘energy storage plant’ occurring in the sub-equations is meant to refer to one energy storage unit delivered to the markets.
GHG emission avoidance

\[ \Delta \text{GHG}_{\text{abs,storage}} = \Sigma_{y=1}^{10} (\text{Ref}_{\text{energy},y} + \text{Ref}_{\text{services},y}) - \Sigma_{y=1}^{10} \text{Proj}_{\text{energy},y} \]  

[5.1]

\[ \Delta \text{GHG}_{\text{abs,storage}} = \Sigma_{y=1}^{10} N_y \times (\text{Ref}_{\text{energy},y} + \text{Ref}_{\text{services},y}) - \Sigma_{y=1}^{10} N_y \times \text{Proj}_{\text{energy},y} \]  

[5.2]

Where:

\( \text{Ref}_{\text{energy},y} \) = Energy-related GHG emissions present in the reference scenario in year \( y \) that will not occur due to the energy storage plant put in place, in tonnes CO\(_2\). This includes direct emissions from the use of fossil fuels and generation of heat, indirect emissions from the use of grid electricity and grid heat, process-related emissions from the production of hydrogen as well as from transmission losses associated with the grid transport. It shall be calculated according to Equation [5.3] below.

\( \text{Ref}_{\text{services},y} \) = Auxiliary-services-related GHG emissions present in the reference case in year \( y \) that will not occur due to the energy storage plant put in place, in tonnes CO\(_2\). This includes direct emissions from the use of fossil fuels and generation of heat, in particular from inefficient use of primary energy, indirect emissions from the use of grid electricity and grid heat as well as from transmission losses associated with the grid transport. It shall be calculated according to Equation [5.4] below.

\( \text{Proj}_{\text{energy},y} \) = Energy-related GHG emissions not present in the reference scenario in year \( y \) that will occur due to the provision of energy by the energy storage plant, in tonnes CO\(_2\). This includes direct emissions from the use of fossil fuels and generation of heat, indirect emissions from the use of grid electricity and grid heat, process-related emissions from the production of hydrogen as well as from transmission losses associated with the grid transport. It shall be calculated according to Equation [5.5] below.

\( N_y \) = number of energy storage units supplied to markets by the proposed production facility of energy storage units, in year \( y \). The applicant shall estimate this based on the expected output of the production facility and the current market potential.

\( y \) = year of operation.

<table>
<thead>
<tr>

</tr>
<tr>
<td></td>
<td></td>
<td>[5.3]</td>
</tr>
</tbody>
</table>

Where:

\( X \) = number of energy types considered. This includes all energy types replaced, in particular all kinds of energy carriers as well as energy types with associated indirect GHG emissions such as electricity and heat.

\( E_{\text{out},y,x} \) = secondary energy supplied to energy grids or final energy delivered to end-user of energy type \( x \), in year \( y \), in terra Joules (TJ). For the application, this shall be estimated by the applicant based on the foreseen operation of the energy storage plant in line with the planned storage capacity, storing cycles as well as the rated input and output power. For the situations where funding will be used to finance the construction of a manufacturing plant of innovative technologies’ components, it shall be estimated based on forecasted capacity, load factor and operating hours that the innovative technology(ies) or component(s) will be able to generate when implemented.
EF_{out,y,x} = emission factor for the energy displaced by the output of the energy storage plant of energy type x, in year y, in tonnes CO$_2$/TJ. For the emission factors, the values presented in Table 5.2 shall be applied as the default case. If the energy is delivered to a predefined set of end-users with a reference emission intensity deviating from the default case, the applicant shall use an emission intensity tied to the specific case, providing verifiable information on it.

$\Theta_x$ = mean losses from transport of energy type x, in percent. As long as no regulation prescribes the use of certain values for transport losses, the EU default values presented in Table 5.2 should be applied.

<table>

<td>Ref$_{services,y}$</td>
<td>$\sum_{a=1}^{A} \Delta$EF$<em>{service,a} \cdot T</em>{services,y,a} \cdot R_{services,y,a}$ [5.4]</td>
</tr>
</tbody>
</table>

Where:

A = number of services considered.

$\Delta$EF$_{service,a}$ = mean increase of the emission intensity of grid electricity due to the need for the auxiliary service a, in tonnes CO$_2$ per hours of service delivery and per unit of service (MW, Mvar, GVAs). This is to be estimated by the applicant based on the local grid conditions. The reference case to be considered is the provision of the auxiliary service x by running fossil fuel plants at a less-than-optimal efficiency.

$T_{services,y,a}$ = the amount of hours that the provision of the auxiliary service a is required in year y, in hours (h). This is to be estimated by the applicant based on the local grid conditions and the current local grid regulation. For the situations where funding will be used to finance the construction of a manufacturing plant of innovative technologies’ components, it shall be estimated based on forecasted operating hours that the innovative technology(ies) or component(s) will be able to generate when implemented.

$R_{services,y,a}$ = rating of the energy storage plant with respect to the service a, in year y, in a unit depending on the service (MW, Mvar, GVAs). This is to be provided by the applicant based on the technical documentation of the foreseen energy storage plant. For the situations where funding will be used to finance the construction of a manufacturing plant of innovative technologies’ components, it shall be estimated based on forecasted total rating that the innovative technology(ies) or component(s) will be able to generate when implemented.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Equation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Proj$_{energy,y}$</td>
<td>$\sum_{x=1}^{X} EF_{in,y,x} \cdot E_{in,y,x} / (1 - \Theta_x)$ [5.5]</td>
</tr>
</tbody>
</table>

Where:

X = number of energy types considered. The applicant needs to include all energy types used, in particular all kinds of energy carriers as well as energy types with associated indirect GHG emissions such as electricity and heat.

$E_{in,y,x}$ = energy used by the energy storage plant of energy type x, in year y, in terra Joules (TJ). This includes both the energy stored in the energy storage plant and its self-consumption of energy. For the proposal, this shall be estimated by the applicant based on the foreseen operation of the energy storage unit in line with the planned storage capacity, storage efficiency, storing cycles and the rated input power. For the situations where funding will be used to finance the construction of a manufacturing plant of innovative technologies’ components, it shall be estimated based on forecasted capacity, load factor and operating hours that the innovative technology(ies) or component(s) will be able to generate when implemented.
EF_{in,y,x} = emission factor of energy type x for the energy used by the energy storage plant, in year y, in terra Joules (TJ). For the emission factors, the values presented in Table 5.2 shall be applied as the default case. If the energy is supplied by a pre-defined set of suppliers with a reference emission intensity deviating from the default case, the applicant shall use an emission intensity tied to the specific case, providing verifiable information on it.

\( \Theta_y \) = mean losses from transport of energy type x, in percent. As long as no regulation prescribes the use of certain values for transport losses, the EU default values presented in Table 5.2 should be applied.

### 5.3.2 Second stage methodologies

During the second stage of application, the absolute GHG emission avoidance by an energy storage plant shall be calculated according to Equation [5.6]. For a production facility that produces energy storage units, the absolute GHG emission avoidance plant shall be calculated according to Equation [5.7].

\[
\Delta \text{GHG}_{\text{abs}} = \sum_{y=1}^{10} \left( \text{Ref}_{\text{energy},y} + \text{Ref}_{\text{services},y} \right) - \sum_{y=1}^{10} \left( \text{Proj}_{\text{energy},y} + \text{Proj}_{\text{on-site},y} \right)
\]  

[5.6]

\[
\Delta \text{GHG}_{\text{abs}} = \sum_{y=1}^{10} N_y \times \left( \text{Ref}_{\text{energy},y} + \text{Ref}_{\text{services},y} \right) - \sum_{y=1}^{10} N_y \times \text{Proj}_{\text{energy},y}
\]  

[5.7]

For the second stage, the same calculations rules for \( \text{Ref}_{\text{energy},y}, \text{Ref}_{\text{services},y}, \text{Proj}_{\text{energy},y} \) apply (see Equations [5.3] to [5.5] above). The calculations from the first stage of application shall be updated, if any of the required input data has changed between the first and second stage of application.

\( \text{Proj}_{\text{on-site,y}} \) = Emissions from storage of energy carriers and their transport by pipelines, road or maritime modals in year y, in tonnes CO\textsubscript{2}e. This includes emissions from combustion at the vehicles, and other processes at installations functionally connected to the transport network including booster stations; fugitive and vented emissions from the transport network. It shall be calculated according to Equation [5.8] below.

\[
\text{Proj}_{\text{on-site,y}} = \text{Proj}_{\text{stat,y}} + \text{Proj}_{\text{mob,y}} + \text{Proj}_{\text{ect,y}} + \text{Proj}_{\text{ug,y}}
\]  

[5.8]

\[
\text{Proj}_{\text{stat,y}} = \sum_{x=1}^{X} \text{EF}_{x,y,x} \times \text{E}_{\text{stat},y,x}
\]  

[5.8a]

\[
\text{Proj}_{\text{mob,y}} = \sum_{x=1}^{X} \text{EF}_{x,y,x} \times \text{E}_{\text{mob},y,x}
\]  

[5.8b]

\[
\text{Proj}_{\text{ug,y}} = \sum_{z=1}^{Z} \text{M}_{\text{ug},y,x} \times \text{GWP}_{\text{ug},z}
\]  

[5.8c]

Where:

X = number of energy types considered. The applicant needs to include all energy types used, in particular all kinds of energy carriers as well as energy types with associated indirect GHG emissions such as electricity and heat.

Z = number of GHGs considered. (see Section 1.3.3).

\( \text{Proj}_{\text{stat,y}} \) = GHG emissions from energy consumption in stationary machinery (except for the energy storage units) at the project site in year y, in tonnes CO\textsubscript{2}e. This should include fuel consumed for processing of materials, generation of electric power and heat, and from auxiliary loads. It shall be calculated according to Equation [5.8a] above.
\( \text{Proj}_{\text{mob},y} \) = GHG emissions from energy consumption from on-site vehicles and other transportation at the project site, in year \( y \), in tonnes CO\(_2\)e. This includes vehicles used for regular maintenance. It shall be calculated according to Equation [5.8b] above.

\( \text{Proj}_{\text{fug},y} \) = GHG emissions from fugitive greenhouse gas emissions at the project site in year \( y \), in tonnes CO\(_2\)e. It shall be calculated according to Equation [5.8c] above.

\( E_{\text{stat},y,x} \) = Quantity of energy type \( x \) used in stationary sources at the project site in year \( y \), in TJ. For the proposal, this shall be estimated by the applicant based on the foreseen operation of the energy storage unit in line with the planned storage capacity, storage efficiency, storing cycles and the rated input power. For the situations where funding will be used to finance the construction of a manufacturing plant of innovative technologies’ components, it shall be estimated based on forecasted energy use that the innovative technology(ies) or component(s) will require when implemented.

\( E_{\text{mob},y,x} \) = Quantity of energy type \( x \) used in mobile sources at the project site in year \( y \), in TJ. For the proposal, this shall be estimated by the applicant based on the foreseen operation of the energy storage unit in line with the planned storage capacity, storage efficiency, storing cycles and the rated input power. For the situations where funding will be used to finance the construction of a manufacturing plant of innovative technologies’ components, it shall be estimated based on forecasted energy use that the innovative technology(ies) or component(s) will require when implemented.

\( EF_{\text{in},x} \) = Emission factor due to the use of the energy type \( x \), in tonnes CO\(_2\)e/ TJ. The applicable \( EF \) presented in Table 5.2 should be applied.

\( M_{\text{fug},y,z} \) = Amount of the fugitive emissions of greenhouse gas \( z \) at the project site in year \( y \), in tonnes. For the proposal, this shall be estimated by the applicant based on the foreseen operation of the energy storage unit in line with the planned storage capacity, storage efficiency, storing cycles and the rated input power. For the situations where funding will be used to finance the construction of a manufacturing plant of innovative technologies’ components, it shall be estimated based on forecasted fugitive emissions that the innovative technology(ies) or component(s) will result in when implemented.

\( \text{GWP}_{\text{fug},z} \) = Global Warming Potential of the fugitive greenhouse gas \( z \). See section 1.3.3).

### 5.4 Data and parameters

The table below presents the parameters that will be deemed as constant throughout the duration of the project and, consequently, shall not be monitored.

5.5 Monitoring, reporting and verification of performance for disbursement and knowledge-sharing

A monitoring plan consisting of a detailed, complete and transparent documentation of the parameters used in calculations and data sources shall be submitted already at first stage of the application. This document shall contain at least the elements laid down in Equations [5.3] to [5.8].

The verification of achieved GHG emission avoidance will be based on the annual aggregation of the hourly output profiles, using the same equations and default parameters as during the proposal stage.

Table 5.3 presents the parameters that, at minimum, shall be monitored throughout the project and be part of the project’s monitoring and reporting plan.

All measurements should be conducted with calibrated measurement equipment according to relevant industry standards.

In addition, at entry into operation, the applicant will need to provide technical documentation of the energy storage plant and its connections to end-users and energy grids, including the current local grid conditions with respect to renewable energy, grid congestions and auxiliary service requirements.

For the situations where funding will be used to finance the construction of a manufacturing plant of innovative technologies’ components, applicants shall demonstrate at the application the contractual arrangements with customers (i.e. companies that will run the innovative energy storage technology).

In addition to the parameters listed above, the following parameters will be monitored and reported for **knowledge sharing purposes** where applicable:

- Energy supplied by each individual energy storage unit (per annum).
- Hourly profiles for use and feed-in of grid electricity.
- Hourly profiles for generation of electricity delivered to the project from PPAs.
- Hourly profiles for avoided curtailment based on final physical notifications of co-located RES plants or grid operator instructions.
- Hourly profiles for provided system services.
- Reliability expressed according to reliability indicators such as Energy Not Supplied.
- Improvement in voltage variation in the grid and length of voltage variation attributable to the Project versus reference system.
- Total Loss of Power, Restoration Time, Equivalent Time of Interruption.
- High-level mapping of environmental impacts and mitigation measures.
- High-level risk screening and mitigation measures.
- Lessons learned and experiences.

The detailed knowledge-sharing requirements are spelled out in the Model Grant Agreement, call text and knowledge-sharing plan template.

### A1.5 Innovative solutions for procurement of renewable electricity

Examples for successful solutions for the procurement of additional renewable electricity could include among others:

- Electricity supplied by a direct connection to a dedicated renewable source, not connected to the grid;
- Wind electricity delivered by the grid, that would otherwise be curtailed;
- Hydroelectricity that has insufficient demand in the region and will probably be insufficiently connected to the rest of the grid even in 2030 to allow all of it to be used;
- Renewable electricity supplied under a Power Purchase Agreement (PPA) via the grid if the following conditions are satisfied:
  - The project contracts a utility to supply renewable electricity from a particular renewable energy installation or installations (e.g. wind farm).
  - The power (MW) used at any time under the PPA should not exceed the power that is being generated by the renewable energy installation(s)
  - The grid connection between producer and user of the electricity does not pass a zone of grid congestion for electricity passing in the same direction as attested by the grid operator.

To avoid negative impacts on the functioning of the electricity market, applicants should at least prove that the procurement of renewable electricity does not lead to additional congestion.

This annex should be read in conjunction with section 2.2.3 on inputs in industrial projects.

### A1.6 Energy efficiency and circular economy objectives

Actions that contribute to **energy efficiency and circular economy objectives** are likely to involve one or more of the following:

(i) **Increased energy and resource efficiency and reduced impact on water use** including through adoption of circular business models within and between industrial facilities.
(incl. industrial symbiosis) and through using less water/reuse/recycling of wastewater; or

(ii) **increased durability, functionality, modularity, upgradability, easy disassembly and/or repair**, or

(iii) **recovery of materials and energy from waste and wastewater, including biomass waste and residues** e.g. as food, feed, nutrients, fertilisers, biobased materials or chemical feedstock; or

(iv) **substitution of virgin materials with secondary raw materials and by-products** or

(v) development and sustainable production of new **materials** (including bio-based materials) that are reusable, recyclable or compostable; or use of materials that are reusable and recyclable; or

(vi) **reuse, repair, refurbishing, repurposing and remanufacturing** of end-of-life or redundant products, movable assets and their components that would otherwise be discarded or immovable assets (buildings / infrastructure / facilities)

The applicants shall justify the above with quantitative indicators to the extent possible always with regard to a reference scenario or the best available technology, for example:

- the estimated primary energy avoidance of the proposed action in comparison to the reference scenario in percent;
- in case of (net) energy recovery, amount of energy that can be produced;
- quantity of virgin raw material saved;
- the increase of recycled content in new products compared to baseline;
- quantity of materials recovered;
- volume of water reused or recycled.

These indicators will be based on a life-cycle assessment (LCA) where this is available. The baseline and LCA methodology should be described. In general, projects should give information at unit level (e.g. for each product, service, process or installation) and what is expected to be achieved at the end of the project (e.g. products, services or processes in the market).

### A1.7 Definitions

For the purpose of this methodology, the following definitions apply:

1. ‘accuracy’ means the closeness of the agreement between the result of a measurement and the true value of the particular quantity or a reference value determined empirically using internationally accepted and traceable calibration materials and standard methods, taking into account both random and systematic factors.

2. ‘activity data’ means data on the amount of fuels or materials consumed or produced by a process relevant for the calculation-based monitoring methodology, expressed in terajoules, mass in tonnes or (for gases) volume in normal cubic metres, as appropriate.

3. ‘auxiliary services to electricity grids’ mean services required for the operation of electricity grids such as the provision of reserve power, reactive power, inertia, frequency response and similar.

4. ‘bio-electricity’ means electricity generated from biomass-derived fuels

5. ‘biofuels’ means liquid fuel, suitable for transport use, produced from biomass.
‘biogas’ means gaseous fuels produced from biomass.

‘bio-heat’ means heating or cooling from biomass-derived fuels.

‘bioliquids’ means liquid fuel for energy purposes other than for transport, including electricity and heating and cooling, produced from biomass.

‘biomass-derived fuels’ include biomass, solid biofuels, bioliquids, liquid biofuels, biogas and biomethane, in the meanings of REDII.

‘biomass’ means the biodegradable fraction of products, waste and residues from biological origin from agriculture, including vegetal and animal substances, from forestry and related industries, including fisheries and aquaculture, as well as the biodegradable fraction of waste, including industrial and municipal waste of biological origin.

‘calculation factors’ means net calorific value, emission factor, preliminary emission factor, oxidation factor, conversion factor, carbon content or biomass fraction.

‘calibration’ means the set of operations, which establishes, under specified conditions, the relations between values indicated by a measuring instrument or measuring system, or values represented by a material measure or a reference material and the corresponding values of a quantity realised by a reference standard.

‘CO2 capture’ means the activity of capturing from gas streams CO2 that would otherwise be emitted.

‘CO2 transport’ means the transport of CO2 for use or storage.

‘combustion emissions’ means greenhouse gas emissions occurring during the exothermic reaction of a fuel with oxygen.

‘emission factor’ means the average emission rate of a greenhouse gas relative to the activity data of a source stream assuming complete oxidation for combustion and complete conversion for all other chemical reactions.

‘emission source’ means a separately identifiable part of an installation or a process within an installation, from which relevant greenhouse gases are emitted.

‘emissions intensity’ is also known, for transport fuels, as well-to-wheels emissions: it comprises not only combustion emissions, but also all the GHG emissions from the supply chain that supplies the product: extraction of raw materials, all steps in the processing, transport and distribution.

‘energy from renewable sources’ or ‘renewable energy’ means energy from renewable non-fossil sources, namely wind, solar (solar thermal and solar photovoltaic) and geothermal energy, ambient energy, tide, wave and other ocean energy, hydropower, biomass, landfill gas, sewage treatment plant gas, and biogas.

‘energy storage plant/unit’ means an energy storage plant/unit is a facility that stores a certain type of energy. Several energy storage units at one site comprise one energy storage plant, whereas an energy storage unit is characterized by the fact that it can operate independently from other energy storage units at the same site. Where several identical energy storage units (i.e. with the same power rating, age and efficiency) are installed at one site, they may be considered as one single energy storage unit.

‘enhanced hydrocarbon recovery’ means the recovery of hydrocarbons in addition to those extracted by water injection or other means.

‘EU ETS product benchmark’ is based on the average GHG emissions of the best performing 10% of the installations producing that product in the EU and EEA-EFTA states. They refer to the direct GHG emissions from the final process in a production chain that produces a unit quantity of a defined product, using a particular process whose boundary is defined. It is only part of the emissions intensity of the product, because it does not consider...
emissions from previous production stages (usually covered by other benchmarks) or from supplying inputs (or the combustion emissions of the product itself). The benchmark may comprise emissions from several sub-installations.\(^{19}\) The relevant benchmarks are those applicable at the time of submission of the application whether at first or second stage.

(24) ‘fossil carbon’ means inorganic and organic carbon that is not biomass.

(25) ‘fugitive emissions’ means irregular or unintended emissions from sources that are not localised, or too diverse or too small to be monitored individually.

(26) ‘generator rating’ means the generator rating of an energy storage unit is the maximum power, expressed in Watts or one of its multiples, for which the energy storage unit’s generator has been designed to operate. The generator rating of an energy storage plant is the sum of the generator ratings of its energy storage units.

(27) ‘geological storage of CO2’ means geological storage of CO2 as defined in Article 3(1) of Directive 2009/31/EC.

(28) ‘geothermal energy’ means energy stored in the form of heat beneath the surface of solid earth.

(29) ‘greenfield energy storage plant’ means a new energy storage plant that is constructed and operated at a site where no energy storage plant was operated prior to the implementation of the project activity.

(30) ‘guarantee of origin’ means an electronic document which has the sole function of providing evidence to a final customer that a given share or quantity of energy was produced from renewable sources.

(31) ‘inertia capability’ means the maximum inertia, expressed in Volt-Ampere seconds (VAs) or one of its multiples, which the energy storage unit has been designed to provide at nominal conditions. The inertia capability of an energy storage plant is the sum of the inertia capabilities of its energy storage units.

(32) ‘input power rating (or installed input capacity)’ means the (active) power, expressed in Watts or one of its multiples, for which the energy storage unit has been designed to operate at nominal conditions. The input power rating of an energy storage plant is the sum of the input power ratings of its energy storage units.

(33) ‘installation’ is a stationary technical unit where one or more activities under the scope of the European Union Emissions Trading Scheme (EU ETS) and any other directly associated activities which have a technical connection with the activities carried out on that site and which could have an effect on emissions and pollution.

(34) ‘intra-daily electricity storage’ means all electricity storage units providing auxiliary services to the electricity grid and/or taking part in intra-daily electricity markets.

(35) ‘leakage’ means leakage as defined in Article 3(5) of Directive 2009/31/EC.

(36) ‘measurement system’ means a complete set of measuring instruments and other equipment, such as sampling and data-processing equipment, used to determine variables such as the activity data, the carbon content, the calorific value or the emission factor of the greenhouse gas emissions.

(37) ‘net calorific value’ (NCV) means the specific amount of energy released as heat when a fuel or material undergoes complete combustion with oxygen under standard conditions, less the heat of vaporisation of any water formed.

‘other energy storage’ means all energy storage other than intra-daily electricity storage, in particular including heat / cold storage, gaseous and liquid fuel storage as well as long-term electricity storage.

‘output power rating (or installed output capacity)’ means the (active) power, expressed in Watts or one of its multiples, for which the energy storage unit has been designed to operate at nominal conditions. The output power rating of an energy storage plant is the sum of the output power ratings of its energy storage units.

‘proxy data’ means annual values which are empirically substantiated or derived from accepted sources and which an operator uses to substitute the activity data or the calculation factors for the purpose of ensuring complete reporting when it is not possible to generate all the required activity data or calculation factors in the applicable monitoring methodology.

‘reactive power rating’ means the maximum reactive power, expressed in volt-ampere reactive (var) or one of its multiples, which the energy storage unit has been designed to provide at nominal conditions. The reactive power rating of an energy storage plant is the sum of the reactive power ratings of its energy storage units.

‘renewable liquid and gaseous transport fuels of non-biological origin’ means liquid or gaseous fuels which are used in the transport sector other than biofuels or biogas, the energy content of which is derived from renewable sources other than biomass.

‘renewables power purchase agreement’ means a contract under which a natural or legal person agrees to purchase renewable electricity directly from an electricity producer.

‘reporting period’ means a calendar year during which emissions have to be monitored and reported.

‘repowering’ means renewing power plants that produce renewable energy, including the full or partial replacement of installations or operation systems and equipment for the purposes of replacing capacity or increasing the efficiency or capacity of the installation.

‘storage site’ means storage site as defined in Article 3(3) of Directive 2009/31/EC.

‘tonnes of CO2e’ means metric tonnes of CO2 or CO2e.

‘transport network’ means transport network as defined in Article 3(22) of Directive 2009/31/EC.

‘vented emissions’ means emissions deliberately released from an installation by provision of a defined point of emission.

‘waste’ means waste as defined in point (1) of Article 3 of Directive 2008/98/EC, excluding substances that have been intentionally modified or contaminated in order to meet this definition.
